

Test Task for Front-End Developer Role

Minimum Requirements

Create a web application based on Angular or React Framework. The application should have two separate pages (routes), Landing (default) and Detail.

- Landing page should provide an ability to enter a search string and perform a search. As part of the search process, the page should query Github AP for available Github repositories matching the string and display the results.
- Clicking on the result should navigate the user to the second page, which will display selected repository information in more details.
- Please use Material Design components inside your web application.

The purpose of the test task is to demonstrate your skills in writing code. Some parts of the Test Task are intentionally vague. Details of the implementation you need to figure out yourself. We value your creativity and problem solving skills.

Good Luck!

Bonus

As a bonus or extra, please complete any (or all) of the following:

- Add an option to the Landing page to accept the search string as a query parameter.
- Use Debouncing technique when performing the search.
- Provide an option to display results in Tabular or Card format.
